

Background

1.1 Review of Counting Process

Recall that a *counting process* $N(t)$ is a continuous-time stochastic process satisfying $N(0) = 0$, with càdlàg sample paths and increments $dN(t)$ of size 1 at event times. By the Doob-Meyer decomposition, there exists a unique predictable process $\Lambda(t)$ such that the compensated process $M(t) = N(t) - \Lambda(t)$ is a mean-zero martingale. The *compensator*, or cumulative intensity, is expressible as:

$$\Lambda(t) = \int_0^t \lambda(s) ds,$$

where $\lambda(s)$ is a predictable intensity process.

In differential form:

$$dM(t) = dN(t) - \lambda(t)dt. \quad (1.1)$$

Since $M(t)$ is a mean-zero martingale:

$$\mathbb{E}\{dM(t)|\mathcal{F}(t-)\} = 0,$$

and since $\lambda(s)$ is a predictable process:

$$\lambda(t)dt = \mathbb{E}\{dN(t)|\mathcal{F}(t-)\}.$$

1.1.1 Optional and Predictable Variations

The variance of a mean-zero martingale is the expectation of its optional and predictable variation processes:

$$\mathbb{V}\{M(t)\} = \mathbb{E}[M^2(t)] = \mathbb{E}[\langle M(t) \rangle].$$

The optional variation of the stochastic integral of a predictable process $H(s)$ with respect to a mean-zero counting process martingale is:

$$\left[\int_0^t H(s) dM(s) \right] = \int_0^t H^2(s) d[M(s)] = \int_0^t H^2(s) dN(s).$$

The predictable variation is:

$$\left\langle \int_0^t H(s) dM(s) \right\rangle = \int_0^t H^2(s) d\langle M(s) \rangle = \int_0^t H^2(s) d\Lambda(s).$$

1.1.2 Standard Brownian Motion

Definition 1.1. Standard **Brownian motion** is a Gaussian process $W : [0, \infty) \rightarrow \mathbb{R}$ with these properties:

- Boundary condition: $W(0) = 0$.
- Moments: $\mathbb{E}\{W(t)\} = 0$ and $\mathbb{C}\{W(s), W(t)\} = \min(s, t)$.
- Continuous sample paths.
- Independent, stationary increments.

■

Discussion 1.1. Let $W(t)$ denote standard Brownian motion.

- The independent increments property means that for any $0 = t_0 < t_1 < \dots < t_n$, the differences:

$$\Delta_1 = W(t_1) - W(t_0), \quad \Delta_2 = W(t_2) - W(t_1), \quad \dots, \quad \Delta_n = W(t_n) - W(t_{n-1}),$$

are independent.

- The stationary increments property means that for any $s \leq t$:

$$W(t) - W(s) \stackrel{d}{=} W(t - s).$$

- The optional and predictable variations of $W(t)$ coincide and are equal to t :

$$[W(t)] = \langle W(t) \rangle = t.$$

- Both $W(t)$ itself and $W^2(t) - t$ are zero-mean martingales.

♠

1.1.3 Martingale Central Limit Theorem

Theorem 1.1. Suppose $M^{(n)}(t)$ is a sequence of mean-zero martingales defined on $[0, \tau]$, and for any $\epsilon > 0$ let $M_\epsilon^{(n)}(t)$ denote the martingale containing all jumps of $M^{(n)}(t)$ that are of size greater than ϵ . If the following conditions hold:

- $\langle M^{(n)} \rangle \xrightarrow{p} \sigma^2(t)$ for all $t \in [0, \tau]$ as $n \rightarrow \infty$, where $\sigma^2(t)$ is a strictly increasing continuous function with $\sigma^2(0) = 0$.
- $\langle M_\epsilon^{(n)} \rangle \xrightarrow{p} 0$ for all $t \in [0, \tau]$ for any $\epsilon > 0$ as $n \rightarrow \infty$.

Then, $M^{(n)}(t)$ converges weakly to a Gaussian martingale:

$$M^{(n)}(t) \rightsquigarrow W\{\sigma^2(t)\}.$$

□

1.1.4 Functional Delta Method

Theorem 1.2. Suppose g is a continuously differentiable function, and that for $n \rightarrow \infty$:

$$\sqrt{n}\{\hat{\mu}_n(\cdot) - \mu(\cdot)\} \rightsquigarrow Z(\cdot), \quad (1.2)$$

where $Z(\cdot)$ has continuous sample paths. Then:

$$\sqrt{n}\{g \circ \hat{\mu}_n(\cdot) - g \circ \mu(\cdot)\} \rightsquigarrow \{g' \circ \mu(\cdot)\}Z(\cdot)$$

and:

$$\sqrt{n}\{g \circ \hat{\mu}_n(\cdot) - g \circ \mu(\cdot)\} = \{g' \circ \mu(\cdot)\} \cdot \sqrt{n}\{\hat{\mu}_n(\cdot) - \mu(\cdot)\} + o_p(1).$$

□

1.2 Data

Let $\{(U_i, \delta_i)\}_{i=1}^n$ denote IID observations, where:

$$U_i = \min(C_i, T_i), \quad \delta_i = \mathbb{I}(T_i \leq C_i).$$

Define the individual-level *event* and *at-risk* processes:

$$N_i(t) = \mathbb{I}(U_i \leq t, \delta_i = 1), \quad Y_i(t) = \mathbb{I}(U_i \geq t).$$

The intensity of $N_i(t)$ will take the form:

$$\lambda_i(t) = \alpha(t)Y_i(t),$$

where $\alpha(t)$ is the hazard of the event-time distribution.

Denote the aggregated, sample-level processes by:

$$N(t) = \sum_{i=1}^n N_i(t), \quad Y(t) = \sum_{i=1}^n Y_i(t), \quad \lambda(t) = \sum_{i=1}^n \lambda_i(t).$$

The aggregated intensity process satisfies the multiplicative property:

$$\lambda(t) = \alpha(t)Y(t). \quad (1.3)$$

Nelson-Aalen

2.1 Cumulative Hazard

Definition 2.1. The **cumulative hazard** may be defined as:

$$A(t) = - \int_0^t \frac{dS(u)}{S(u-)}.$$
 (2.1)

■

Discussion 2.1. The survival increment is interpretable as:

$$-dS(t) = S(t-) - S(t) = \mathbb{P}(t \leq T < t + dt).$$

If the distribution of T is absolutely continuous, then $-dS(t) = f(t)dt$ and $S(t-) = S(t)$, such that (2.1) reduces to:

$$A(t) = \int_0^t \frac{f(u)}{S(u)} du = \int_0^t \alpha(u) du,$$

where $\alpha(u)$ is the continuous hazard.

If the distribution is discrete, then $-dS(t) = S(t-) - S(t) = \mathbb{P}(T = t)$ and:

$$\frac{-dS(t)}{S(t-)} = \frac{\mathbb{P}(T = t)}{\mathbb{P}(T \geq t)} = \alpha(t).$$

Thus, in the discrete case,

$$A(t) = \sum_{u \leq t} \alpha(u),$$

where $\alpha(u)$ is the discrete hazard.

The differential form of (2.1) is:

$$dS(t) = -S(t-)dA(t).$$
 (2.2)

♠

2.2 Estimator

Definition 2.2. The **Nelson-Aalen** estimator of the cumulative hazard is:

$$\hat{A}(t) = \int_0^t \frac{J(s)}{Y(s)} dN(s).$$

where $J(t) = \mathbb{I}\{Y(t) > 0\}$, and $J(t)/Y(t) = 0$ if $Y(t) = 0$.

■

Proposition 2.1. Define the *modified cumulative hazard*:

$$A^*(t) = \int_0^t J(s)\alpha(s)ds, \quad (2.3)$$

then:

$$\hat{A}(t) - A^*(t) = \int_0^t \frac{J(s)}{Y(s)} dM(s). \quad (2.4)$$

where $M(s)$ is the counting process martingale corresponding to $N(s)$. ◆

Proof. From (1.1) and (1.3):

$$dN(s) - \alpha(s)Y(s)ds = dM(s).$$

Multiplying by $J(s)/Y(s)$ and integrating over $[0, t]$:

$$\int_0^t \frac{J(s)}{Y(s)} dN(s) - \int_0^t J(s)\alpha(s)ds = \int_0^t \frac{J(s)}{Y(s)} dM(s).$$

■

Corollary 2.1. Since the RHS of (2.4) is the stochastic integral of a predictable process with respect to a mean-zero martingale, the Nelson-Aalen estimator $\hat{A}(t)$ is unbiased for $A^*(t)$:

$$\mathbb{E}\{\hat{A}(t) - A^*(t)\} = 0.$$

♣

Corollary 2.2. An estimate for $\mathbb{V}\{\hat{A}(t) - A^*(t)\}$ is given by:

$$\hat{\sigma}_{\text{NA}}^2(t) = \int_0^t \frac{J(s)}{Y^2(s)} dN(s). \quad (2.5)$$

♣

Proof. The optional variation of (2.4) is:

$$[\hat{A}(t) - A^*(t)] = \int_0^t \left\{ \frac{J(s)}{Y(s)} \right\}^2 d[M(s)] = \int_0^t \frac{J(s)}{Y^2(s)} dN(s).$$

■

2.3 Asymptotics

Proposition 2.2 (Consistency). If $\inf_{s \in [0, \tau]} Y(s) \xrightarrow{p} \infty$ as $n \rightarrow \infty$, then:

$$\sup_{t \in [0, \tau]} |\hat{A}(t) - A(t)| \xrightarrow{p} 0. \quad (2.6)$$

See [0] (IV.1.1). ◆

Proposition 2.3 (Asymptotic Normality). Let $A^*(t) = \int_0^t J(s) dA(s)$ denote the modified cumulative hazard, and $\hat{A}(t)$ the Nelson-Aalen estimator. Suppose there exists a deterministic function $y(s) = \text{plim}_{n \rightarrow \infty} n^{-1}Y(s)$ strictly positive on $[0, \tau]$. The normalized process $\sqrt{n}\{\hat{A}(t) - A^*(t)\}$ converges weakly to a Gaussian martingale:

$$\sqrt{n}\{\hat{A}(t) - A^*(t)\} \rightsquigarrow W\{\sigma_{\text{NA}}^2(t)\}, \quad (2.7)$$

with variance function:

$$\sigma_{\text{NA}}^2(t) = \int_0^t \frac{\alpha(s)}{y(s)} ds.$$

Moreover,

$$\sup_{s \in [0, \tau]} |n \cdot \hat{\sigma}_{\text{NA}}^2(s) - \sigma_{\text{NA}}^2(s)| \xrightarrow{p} 0,$$

where $\hat{\sigma}_{\text{NA}}^2(t)$ is the optional variation estimator (2.5). See [0] (IV.1.2). ◆

Proof (Sketch). Consider the normalized difference:

$$\sqrt{n}\{\hat{A}(t) - A^*(t)\} \equiv \int_0^t H(s) dM(s),$$

where $H(s)$ is the predictable process:

$$H(s) = \sqrt{n} \frac{J(s)}{Y(s)}$$

The predictable variation is:

$$\begin{aligned} \langle \sqrt{n}\{\hat{A}(t) - A^*(t)\} \rangle &= \int_0^t \{H(s)\}^2 d\langle M(s) \rangle \\ &= \int_0^t \frac{J(s)}{n^{-1}Y^2(s)} d\Lambda(s) \\ &= \int_0^t \frac{J(s)}{n^{-1}Y^2(s)} Y(s) \alpha(s) ds \\ &= \int_0^t \frac{J(s)}{n^{-1}Y(s)} \alpha(s) ds. \end{aligned}$$

By hypothesis $n^{-1}Y(s) \xrightarrow{p} y(s)$, which is strictly positive on $[0, \tau]$, hence $J(s) \xrightarrow{p} 1$ and:

$$\text{plim}_{n \rightarrow \infty} \langle \sqrt{n}\{\hat{A}(t) - A^*(t)\} \rangle = \int_0^t \text{plim}_{n \rightarrow \infty} \frac{J(s)}{n^{-1}Y(s)} \alpha(s) ds = \int_0^t \frac{\alpha(s)}{y(s)} ds. \quad \blacksquare$$

2.4 Confidence Bands

Proposition 2.4 (Gill Band). A simultaneous level $(1 - \alpha)$ confidence band for $A^*(t)$ and $t \in [0, \tau]$ is given by:

$$\hat{A}(t) - \frac{\gamma_{1-\alpha} \hat{\sigma}_{\text{NA}}(\tau)}{\sqrt{n}} \leq A^*(t) \leq \hat{A}(t) + \frac{\gamma_{1-\alpha} \hat{\sigma}_{\text{NA}}(\tau)}{\sqrt{n}},$$

where $\gamma_{1-\alpha}$ is a critical value such that:

$$\mathbb{P} \left\{ \sup_{u \in [0,1]} |W(u)| \leq \gamma_{1-\alpha} \right\} = 1 - \alpha.$$

◆

Proof. Recall that $\sqrt{n}\{\hat{A}(t) - A^*(t)\}$ converges weakly to a Gaussian martingale:

$$\sqrt{n}\{\hat{A}(t) - A^*(t)\} \rightsquigarrow W\{\sigma_{\text{NA}}^2(t)\}.$$

Since $\sigma_{\text{NA}}^2(t)$ is monotone increasing:

$$\sup_{t \in [0, \tau]} \left\{ \frac{\sqrt{n}}{\hat{\sigma}_{\text{NA}}(\tau)} |\hat{A}(t) - A^*(t)| \right\} \xrightarrow{\mathcal{L}} \sup_{t \in [0, \tau]} \left| W \left\{ \frac{\sigma_{\text{NA}}^2(t)}{\sigma_{\text{NA}}^2(\tau)} \right\} \right| = \sup_{u \in [0,1]} |W(u)|.$$

Let $\gamma_{1-\alpha}$ denote a critical value such that:

$$\mathbb{P} \left\{ \sup_{u \in [0,1]} |W(u)| \leq \gamma_{1-\alpha} \right\} = 1 - \alpha,$$

then:

$$\begin{aligned} 1 - \alpha &\doteq \mathbb{P} \left\{ \sup_{t \in [0, \tau]} \frac{\sqrt{n}}{\hat{\sigma}_{\text{NA}}(\tau)} |\hat{A}(t) - A^*(t)| \leq \gamma_{1-\alpha} \right\} \\ &= \mathbb{P} \left\{ \hat{A}(t) - \frac{\gamma_{1-\alpha} \hat{\sigma}_{\text{NA}}(\tau)}{\sqrt{n}} \leq A^*(t) \leq \hat{A}(t) + \frac{\gamma_{1-\alpha} \hat{\sigma}_{\text{NA}}(\tau)}{\sqrt{n}} \text{ for } \forall t \in [0, \tau] \right\} \end{aligned}$$

■

Definition 2.3. The standard **Brownian bridge** is a Gaussian process $B : [0, 1] \rightarrow \mathbb{R}$ with these properties:

- Boundary conditions: $B(0) = B(1) = 0$.
- Moments: $\mathbb{E}\{B(t)\} = 0$ and $\mathbb{C}\{B(s), B(t)\} = \min(s, t) - st$.
- Continuous sample paths.

■

Proposition 2.5. Let $W(t)$ denote standard Brownian motion, and define:

$$B(t) = (1 - t)W\left(\frac{t}{1 - t}\right), \quad (2.8)$$

with $B(1) \equiv 0$. Then $B(t)$ is the standard Brownian bridge. ◆

Proof. The boundary conditions are satisfied since $B(0) = W(0) = 0$ and $B(1) = 0$. The mean of $B(t)$ is:

$$\mathbb{E}\{B(t)\} = \mathbb{E}\left\{(1 - t)W\left(\frac{t}{1 - t}\right)\right\} = 0,$$

since $\mathbb{E}\{W(\cdot)\} = 0$. Noting that $s/(1 - s) < t/(1 - t)$:

$$\begin{aligned} \mathbb{C}\{B(s), B(t)\} &= \mathbb{C}\left\{(1 - s)W\left(\frac{s}{1 - s}\right), (1 - t)W\left(\frac{t}{1 - t}\right)\right\} \\ &= (1 - s)(1 - t)\mathbb{C}\left\{W\left(\frac{s}{1 - s}\right), W\left(\frac{t}{1 - t}\right)\right\} \\ &= (1 - s)(1 - t)\frac{s}{1 - s} = s(1 - t) \\ &= \min(s, t) - st. \end{aligned}$$

$B(\cdot)$ has continuous sample paths since $W(\cdot)$ has continuous sample paths and $(1 - t)$ is continuous with $(1 - t) \rightarrow 0$ as $t \rightarrow 1$. ■

Proposition 2.6. Define:

$$K(t) = \frac{\sigma_{\text{NA}}^2(t)}{1 + \sigma_{\text{NA}}^2(t)},$$

and let $q(u)$ denote a continuous, non-negative function on $[0, 1]$. Then,

$$q\{K(t)\} \cdot \{1 - K(t)\} \cdot \sqrt{n}\{\hat{A}(t) - A^*(t)\} \rightsquigarrow q\{K(t)\} \cdot B\{K(t)\}.$$

◆

Proof. Observe that:

$$\sigma_{\text{NA}}^2(t) = \frac{K(t)}{1 - K(t)}.$$

From (2.7):

$$\sqrt{n}\{\hat{A}(t) - A^*(t)\} \rightsquigarrow W\left\{\frac{K(t)}{1 - K(t)}\right\},$$

therefore:

$$q\{K(t)\} \cdot \{1 - K(t)\} \cdot \sqrt{n}\{\hat{A}(t) - A^*(t)\} \rightsquigarrow q\{K(t)\} \cdot \{1 - K(t)\} \cdot W \left\{ \frac{K(t)}{1 - K(t)} \right\}.$$

By (2.8):

$$q\{K(t)\} \cdot \{1 - K(t)\} \cdot W \left\{ \frac{K(t)}{1 - K(t)} \right\} \stackrel{d}{=} q\{K(t)\} \cdot B\{K(t)\}.$$

■

Proposition 2.7.

$$\sup_{t \in [0, \tau]} \left| q\{K(t)\} \cdot \{1 - K(t)\} \cdot \sqrt{n}\{\hat{A}(t) - A^*(t)\} \right| \xrightarrow{\mathcal{L}} \sup_{u \in [0, K(\tau)]} q(u) \cdot |B(u)| \quad (2.9)$$

where $B(\cdot)$ is the standard Brownian bridge. See [0].

◆

Proposition 2.8 (Hall-Wellner Band). A simultaneous level $(1 - \alpha)$ confidence band for $A^*(t)$ and $t \in [0, \tau]$ is given by:

$$\hat{A}(t) - \frac{\gamma_{1-\alpha}\{1 + \sigma_{\text{NA}}^2(t)\}}{\sqrt{n}} \leq A^*(t) \leq \hat{A}(t) + \frac{\gamma_{1-\alpha}\{1 + \sigma_{\text{NA}}^2(t)\}}{\sqrt{n}},$$

where $\gamma_{1-\alpha}$ is a critical value such that:

$$\mathbb{P} \left\{ \sup_{u \in [0, K(\tau)]} |B(u)| \leq \gamma_{1-\alpha} \right\} = 1 - \alpha,$$

◆

Proof. From (2.9) with $q(\cdot) \equiv 1$:

$$\begin{aligned} 1 - \alpha &\doteq \mathbb{P} \left\{ \sup_{t \in [0, \tau]} \left| \{1 - K(t)\} \cdot \sqrt{n}\{\hat{A}(t) - A^*(t)\} \right| \leq \gamma_{1-\alpha} \right\} \\ &= \mathbb{P} \left\{ \sup_{t \in [0, \tau]} \left| \frac{1}{1 + \sigma_{\text{NA}}^2(t)} \cdot \sqrt{n}\{\hat{A}(t) - A^*(t)\} \right| \leq \gamma_{1-\alpha} \right\} \\ &= \mathbb{P} \left\{ \hat{A}(t) - \frac{\gamma_{1-\alpha}\{1 + \sigma_{\text{NA}}^2(t)\}}{\sqrt{n}} \leq A^*(t) \leq \hat{A}(t) + \frac{\gamma_{1-\alpha}\{1 + \sigma_{\text{NA}}^2(t)\}}{\sqrt{n}} \text{ for } \forall t \in [0, \tau] \right\} \end{aligned}$$

■

Proposition 2.9 (Equi-Precision Band). A simultaneous level $(1 - \alpha)$ confidence band for $A^*(t)$ and $t \in [0, \tau]$ is given by:

$$\hat{A}(t) - \frac{\gamma_{1-\alpha}\sigma_{\text{NA}}(t)}{\sqrt{n}} \leq A^*(t) \leq \hat{A}(t) + \frac{\gamma_{1-\alpha}\sigma_{\text{NA}}(t)}{\sqrt{n}},$$

where $\gamma_{1-\alpha}$ is a critical value such that:

$$\mathbb{P} \left\{ \sup_{u \in [0, K(\tau)]} |B(u)| \cdot \{u(1 - u)\}^{-1/2} \leq \gamma_{1-\alpha} \right\} = 1 - \alpha,$$

◆

Proof. Let $q(u) = \{u(1-u)\}^{-1/2}$, then:

$$q\{K(t)\} \cdot \{1 - K(t)\} = \left\{ \frac{\sigma_{\text{NA}}^2}{(1 + \sigma_{\text{NA}}^2)^2} \right\}^{-1/2} \cdot \frac{1}{1 + \sigma_{\text{NA}}^2} = \frac{1}{\sigma_{\text{NA}}}.$$

Now, from (2.9):

$$\begin{aligned} 1 - \alpha &= \mathbb{P} \left\{ \sup_{t \in [0, \tau]} \left| q\{K(t)\} \cdot \{1 - K(t)\} \cdot \sqrt{n} \{ \hat{A}(t) - A^*(t) \} \right| \leq \gamma_{1-\alpha} \right\} \\ &= \mathbb{P} \left\{ \sup_{t \in [0, \tau]} \left| \frac{1}{\sigma_{\text{NA}}(t)} \cdot \sqrt{n} \{ \hat{A}(t) - A^*(t) \} \right| \leq \gamma_{1-\alpha} \right\} \\ &= \mathbb{P} \left\{ \hat{A}(t) - \frac{\gamma_{1-\alpha} \sigma_{\text{NA}}(t)}{\sqrt{n}} \leq A^*(t) \leq \hat{A}(t) + \frac{\gamma_{1-\alpha} \sigma_{\text{NA}}(t)}{\sqrt{n}} \text{ for } \forall t \in [0, \tau] \right\} \end{aligned}$$

■

2.5 Generating Sample Paths

Example 2.1. Recall from (2.4) that:

$$\sqrt{n} \{ \hat{A}(t) - A^*(t) \} = \int_0^t \sqrt{n} \frac{J(s)}{Y(s)} dM(s).$$

Let $H(s) = \sqrt{n} J(s)/Y(s)$ denote the integrand and define the process:

$$\begin{aligned} \Delta(t) &\equiv \sqrt{n} \{ \hat{A}(t) - A^*(t) \} \\ &= \int_0^t H(s) \sum_{i=1}^n dM_i(s) \\ &= \sum_{i=1}^n \left\{ \int_0^t H(s) dM_i(s) \right\}. \end{aligned}$$

To generate approximate sample paths from $\Delta(t)$, consider the process:

$$\Delta^{(b)}(t) \equiv \sum_{i=1}^n Z_i^{(b)} \left\{ \int_0^t H(s) dN_i(s) \right\},$$

where $Z_i^{(b)}$ are IID perturbation weights, with mean 0 and variance 1; for example,

$$Z_i^{(b)} \stackrel{\text{IID}}{\sim} N(0, 1).$$

Practically, the sample path $\Delta^{(b)}(\cdot)$ is a step function, and may be summarized in tabular form. Let $t_1 < \dots < t_K$ denote the distinct observed event times. Then, sample path is completely characterized by $\Delta^{(b)}(t_k)$ for $k \in \{1, \dots, K\}$, where:

$$\Delta^{(b)}(t_k) = \sqrt{n} \sum_{k=1}^K \frac{Z_k^{(b)} \delta_k}{Y(t_k)},$$

where δ_k is the number of events observed at time t_k , and $Z_k^{(b)} \sim N(0, \delta_k)$.

The collection of sample paths:

$$\{\Delta^{(1)}, \dots, \Delta^{(B)}\},$$

may be used to approximate the percentiles for functions of $\Delta(t)$. For example, suppose interest lies in identifying a critical value $\gamma_{1-\alpha}$ such that:

$$\mathbb{P} \left\{ \sup_{t \in [0, \tau]} |\Delta(t)| \leq \gamma_{1-\alpha} \right\} = 1 - \alpha.$$

For each of B iterations,

- i. Generate the perturbation weights $Z_i^{(b)}$.
- ii. Compute and store $M^{(b)} = \sup_{t \in [0, \tau]} |\Delta^{(b)}(t)|$.

Finally, select $\gamma_{1-\alpha}$ as the upper $(1 - \alpha)$ th percentile of the $\{M^{(b)}\}$, then:

$$\hat{A}(t) \pm \frac{\gamma_{1-\alpha}}{\sqrt{n}}$$

is an asymptotic confidence band for $A^*(t)$. ♠

Kaplan-Meier

3.1 Survival Function

Proposition 3.1. Let $0 = t_0 < t_1 < \dots < t_K = t$ partition the interval $(0, t]$. Then:

$$S(t) = \prod_{k=1}^K \mathbb{P}(T > t_k | T > t_{k-1}). \quad (3.1)$$
♦

Proof. By successive conditioning:

$$\begin{aligned} \mathbb{P}(T > t) &= \mathbb{P}(T > t_K) = \mathbb{P}\{(T > t_K) \cap (T > t_{K-1})\} \\ &= \mathbb{P}(T > t_K | T > t_{K-1}) \mathbb{P}(T > t_{K-1}) \\ &= \mathbb{P}(T > t_K | T > t_{K-1}) \mathbb{P}(T > t_{K-1} | T > t_{K-2}) \mathbb{P}(T > t_{K-2}) \\ &= \dots \\ &= \prod_{k=1}^K \mathbb{P}(T > t_k | T > t_{k-1}) \end{aligned}$$

Note that $\mathbb{P}(T > t_1 | T > t_0) = \mathbb{P}(T > t_1)$ since $\mathbb{P}(T > 0) = 1$. ■

Proposition 3.2. Suppose $S(t)$ is the survival function $S(t) = \mathbb{P}(T > t)$ of a positive random variable, and that the *cumulative hazard* is defined as in (2.1). Then,

$$S(t) = \prod_{u \leq t} \{1 - dA(u)\} \equiv \lim_{M \rightarrow 0} \prod_{k=1}^M \{1 - \Delta A(t_k)\},$$

where the limit is over finite partitions of $[0, t]$ as $M = \max_k |t_k - t_{k-1}| \rightarrow 0$. See [0] (II.6.6) for details. $\blacklozenge$

Discussion 3.1. For an absolutely continuous distribution:

$$\mathbb{P}(T > t) = \prod_{u \leq t} \{1 - \alpha(u)du\} = \exp \left\{ - \int_{u \leq t} \alpha(u)du \right\} = e^{-A(t)}.$$

For a discrete distribution:

$$\mathbb{P}(T > t) = \prod_{u \leq t} \{1 - dA(u)\} = \prod_{u \leq t} (1 - \alpha_u).$$

More generally, for a mixed distribution whose cumulative hazard $A(t)$ decomposes as the sum $A(t) = A_C(t) + A_D(t)$ of an absolutely continuous component $A_C(t)$ and a discrete component $A_D(t)$:

$$A_C(t) = \int_0^t \alpha(u)du, \quad A_D(t) = \sum_{u \leq t} \alpha_u,$$

the product integral becomes:

$$S(t) = \prod_{u \leq t} \{1 - \alpha(u)du\} = e^{-A_C(t)} \prod_{u \leq t} \{1 - \alpha_u\}.$$

$\spadesuit$

3.2 Estimator

Definition 3.1. The **Kaplan-Meier** estimator of $S(t)$ is the product integral of the Nelson-Aalen estimator:

$$\hat{S}(t) = \prod_{u \leq t} \{1 - d\hat{A}(t)\}.$$

The Kaplan-Meier estimator is expressible as:

$$\hat{S}(t) = \prod_{k=1}^K \left\{ 1 - \frac{dN(t_k)}{Y(t_k)} \right\},$$

where the finite product is taken across all distinct event times $0 < t_1 < \dots < t_K < \tau$. $\blacksquare$

Definition 3.2. **Greenwood's** estimator for the variance of $\hat{S}(t)$ is:

$$\hat{\sigma}_{\text{KM}}^2(t) = \hat{S}^2(t) \int_0^t \frac{dN(s)}{Y(s)\{Y(s) - dN(s)\}}.$$

$\blacksquare$

3.3 Asymptotics

Proposition 3.3 (Consistency). If $\inf_{s \in [0, \tau]} Y(s) \xrightarrow{p} \infty$ as $n \rightarrow \infty$, then:

$$\sup_{t \in [0, \tau]} |\hat{S}(t) - S(t)| \xrightarrow{p} 0.$$

See [0] (IV.3.1). ◆

Proposition 3.4 (Asymptotic Normality). Define the *modified survival function*:

$$S^*(t) = \prod_{u \leq t} \{1 - dA^*(u)\},$$

and let $\hat{S}(t)$ denote the Kaplan-Meier estimator. Suppose there exists a deterministic function $y(s) = \text{plim}_{n \rightarrow \infty} n^{-1}Y(s)$ strictly positive on $[0, \tau]$. The normalized process $\sqrt{n}\{\hat{S}(t) - S^*(t)\}$ converges weakly to a Gaussian martingale:

$$\sqrt{n}\{\hat{S}(t) - S^*(t)\} \rightsquigarrow W\{\sigma_{\text{KM}}^2(t)\}$$

with variance function:

$$\sigma_{\text{KM}}^2(t) = S^2(t) \int_0^t \frac{\alpha(s)}{y(s)} ds = S^2(t) \sigma_{\text{NA}}^2(t).$$

Moreover,

$$\sup_{s \in [0, \tau]} |n \cdot \hat{\sigma}_{\text{KM}}^2(s) - \sigma_{\text{KM}}^2(s)| \xrightarrow{p} 0,$$

where:

$$\hat{\sigma}_{\text{KM}}^2(t) = \hat{S}^2(t) \int_0^t \frac{J(s)}{Y^2(s)} dN(s),$$

or alternatively Greenwood's estimator. See [0] (IV.3.2) for details. ◆

Proof (Sketch). Consider T absolutely continuous. Let $\tilde{S}(t) = \exp\{-\hat{A}(t)\}$ denote the estimator of $S^*(t)$ obtained by exponentiating the Nelson-Aalen estimator $\hat{A}(t)$. From (2.7) and the functional delta method (1.2):

$$\sqrt{n}\{\tilde{S}(t) - S^*(t)\} \rightsquigarrow -S^*(t) \cdot W\{\sigma_{\text{NA}}^2(t)\}.$$

It can be shown that:

$$\sqrt{n}\{\hat{S}(t) - \tilde{S}(t)\} = o_p(1),$$

therefore:

$$\begin{aligned} \sqrt{n}\{\hat{S}(t) - S^*(t)\} &= \sqrt{n}\{\hat{S}(t) - \tilde{S}(t)\} + \sqrt{n}\{\tilde{S}(t) - S^*(t)\} \\ &= \sqrt{n}\{\tilde{S}(t) - S^*(t)\} + o_p(1) \\ &\rightsquigarrow -S^*(t) \cdot W\{\sigma_{\text{NA}}^2(t)\}. \end{aligned}$$
■

Discussion 3.2 (Kaplan-Meier to Nelson-Aalen). The Kaplan-Meier and Nelson-Aalen estimators are asymptotically related via:

$$\frac{\sqrt{n}\{\hat{S}(t) - S(t)\}}{-S(t)} = \sqrt{n}\{\hat{A}(t) - A(t)\} + o_p(1).$$

Using the martingale representation of the Nelson-Aalen estimator:

$$\frac{\sqrt{n}\{\hat{S}(t) - S(t)\}}{-S(t)} = \int_0^t \frac{\sqrt{n}}{Y(s)} dM(s) + o_p(1).$$

3.4 Confidence Bands

Discussion 3.3. Since $\sqrt{n}\{\hat{A}(t) - A^*(t)\}$ and $\sqrt{n}\{\hat{S}(t) - S^*(t)\}/S^*(t)$ have the same limiting distributions, confidence bands for the Nelson-Aalen estimator may be adapted to provide confidence bands for the Kaplan-Meier estimator. In particular, the *Hall-Wellner band* takes the form:

$$\hat{S}(t) - \frac{\gamma_{1-\alpha}\{1 + \sigma_{\text{NA}}^2(t)\}\hat{S}(t)}{\sqrt{n}} \leq S^*(t) \leq \hat{S}(t) + \frac{\gamma_{1-\alpha}\{1 + \sigma_{\text{NA}}^2(t)\}\hat{S}(t)}{\sqrt{n}},$$

where $\gamma_{1-\alpha}$ is a critical value such that:

$$\mathbb{P} \left\{ \sup_{u \in [0, K(\tau)]} |B(u)| \leq \gamma_{1-\alpha} \right\} = 1 - \alpha,$$

The *equi-precision band* takes the form:

$$\hat{S}(t) - \frac{\gamma_{1-\alpha}\sigma_{\text{NA}}(t)\hat{S}(t)}{\sqrt{n}} \leq S^*(t) \leq \hat{S}(t) + \frac{\gamma_{1-\alpha}\sigma_{\text{NA}}(t)\hat{S}(t)}{\sqrt{n}},$$

where $\gamma_{1-\alpha}$ is a critical value such that:

$$\mathbb{P} \left\{ \sup_{u \in [0, K(\tau)]} |B(u)| \cdot \{u(1-u)\}^{-1/2} \leq \gamma_{1-\alpha} \right\} = 1 - \alpha,$$

3.5 Generating Sample Paths

Example 3.1. Consider the process:

$$\Delta(t) = \sqrt{n}\{\hat{S}(t) - S(t)\}.$$

Sample paths may be generated using the representation:

$$\frac{\sqrt{n}\{\hat{S}(t) - S(t)\}}{-S(t)} = \int_0^t \frac{\sqrt{n}}{Y(s)} dM(s) + o_p(1).$$

In particular:

$$\Delta(t) = \sum_{i=1}^n \int_0^t \left\{ -\frac{\sqrt{n}S(t)J(s)}{Y(s)} \right\} dM_i(s) + o_p(1).$$

Let $Z_i^{(b)}$ denote IID $(0, 1)$ perturbation weights, and define:

$$\Delta^{(b)}(t) = - \sum_{i=1}^n Z_i^{(b)} \left\{ \int_0^t \frac{\sqrt{n}S(t)J(s)}{Y(s)} dN_i(s) \right\}$$

For each of B iterations,

- i. Generate the perturbation weights $Z_i^{(b)}$.
- ii. Compute and store $M^{(b)} = \sup_{t \in [0, \tau]} |\Delta^{(b)}(t)|$.

Finally, select $\gamma_{1-\alpha}$ as the upper $(1 - \alpha)$ th percentile of the $\{M^{(b)}\}$, then:

$$\hat{S}(t) \pm \frac{\gamma_{1-\alpha}}{\sqrt{n}}$$

is an asymptotic confidence band for $S^*(t)$.
